

1
2 **ABSTRACT**

3 In at least one implementation, described herein, P and Q_1, \dots, Q_n are public
4 points on an elliptic curve over a finite field, but the ratios of Q_i to P are private.
5 Those ratios are the components $(\alpha_1, \dots, \alpha_n)$ of a private key, where $Q_i = \alpha_i P$. This
6 implementation generates short digital ciphers (i.e., signatures), at least in part, by
7 mapping a message M to a point T on the elliptic curve and then scaling that point
8 T based upon the private key α to get S . At least one other implementation,
9 described herein, verifies those ciphers by comparing pairing values of two pairs,
10 where one pair is the public point P and the scaled point S and another pair is
11 public Q and the point T . This implementation tests whether $\log(Q)/\log(P) =$
12 $\log(S)/\log(T)$, without computing any elliptic curve discrete logarithm directly.
